Understanding Puberty

Puberty is a natural developmental phase that typically begins between ages 8 and 13 for girls. It is initiated by hormonal changes in the body that prepare the individual for reproductive maturity. Understanding the basics of puberty can help girls feel more at ease as they experience these changes.

The Role of Hormones

During puberty, the body increases the production of hormones such as estrogen and progesterone. These hormones are responsible for the development of secondary sexual characteristics and the regulation of the menstrual cycle. The pituitary gland plays a crucial role in signaling the ovaries to start producing these hormones, leading to various physical and emotional changes.
